

Models of Chemical Bonding

Chemistry Lecture I

Outline I

- Valence Electrons and the Octet Rule
- Bonds- Ionic vs. Covalent
- Lewis Structures - Dashes and Dots
- Formal Charge
- Resonance Structures

Outline II

- Structural Formulas- Condensed and Bond-Line
- Three-Dimensional Formulas
- VSEPR Theory
- Polar Covalent Bonds
- Dipole Moments

Valence e⁻ and the Periodic Table

- **Valence electrons** - Electrons in the outermost electronic level of an atom
- Group # on the Periodic Table indicates how many an element possesses (Roman numeral)

1 IA 1 H Hydrogen 1.0079	2 IIA 4 Be Beryllium 9.0122											13 IIIA 5 B Boron 10.811	14 IVA 6 C Carbon 12.011	15 VA 7 N Nitrogen 14.007	16 VIA 8 O Oxygen 15.999	17 VIIA 9 F Fluorine 18.998	18 VIIIA 2 He Helium 4.0026

The Octet Rule

- **Octet Rule** - The tendency for an atom to achieve a configuration where its valence level contains 8 e⁻
- Based on the idea that atoms without the configuration of a noble gas would react to attain such a configuration
 - Noble gases have full valence levels and are, for the most part, unreactive
 - Atoms of the first row, H and He, usually have 2 e⁻
 - Atoms of the 2nd row, B, C, N, etc., can have 8 e⁻

Types of Bonding

- Atoms may lose or gain valence electrons to become charged species called ions
- Ions may arise from the interaction of atoms of widely differing electronegativities.

- The very electronegative F attracts an e^- from the weakly electronegative Li (called electropositive) to form an ion pair referred to as a **salt**
- **Ionic Bond** - The attractive force between oppositely charged ions

Covalent Bonds

- Covalent bonds form by the sharing of e⁻ between atoms

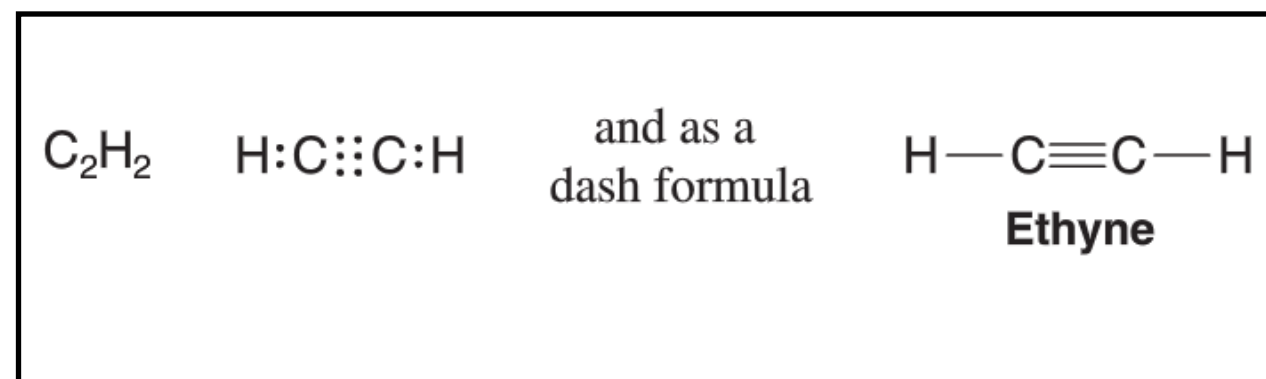

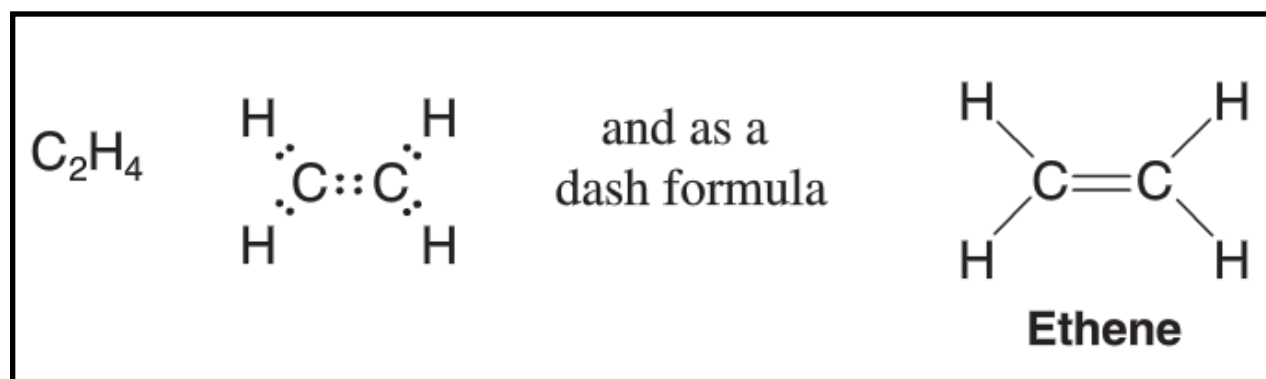

- Molecules are composed of atoms joined exclusively or primarily by covalent bonds

Dash structural formulas

Dash Structural Formulas

- **Dash structural formulas** show *shared* e⁻ pairs as dashes and show the elements using their symbols
- These are often called **Lewis Structures**

Lewis Structure Rules

- Lewis structures only use valence e^-
- The # of valence e^- of a neutral atom is equal to its group number in the periodic table (Carbon has 4)
- If the structure is an **anion** (negatively charged ion), add an e^- for each negative charge
- If the structure is a **cation** (positively charged ion), subtract an e^- for each positive charge
- Give each element the configuration of a noble gas
 - C, N, O, F want 8 (**octet rule!**)
 - H needs 2 e^- to have configuration of He
- Let's try **CH₃F**

Lewis Structure Problems

- CH_3NH_2
- $\text{CH}_3\text{CH}_2\text{OH}$
- CO_3^{2-}
- H_2C_2
- HOCl
- OCl_2
- NO_3^-
- BH_4^-
- C_6H_6

Formal Charge

- Many Lewis structures are incomplete until we assign a formal charge to the atoms
- There are a few ways to do this. I use the formula:
 - $FC = \text{Group\#} - 1/2 \text{ shared } e^- - \text{unshared } e^-$
- The sum of charges on the atoms must equal the overall charge of the molecule
 - Let's try NH_4^+

Formal Charge Problems

- NO_3^-
- I_3^- (does F_3^- exist???)
- CO
- SCN^-
- H_3C^+
- HF_2^-
- O_3

Octet Rule Exceptions

- Atoms in the third row or higher can have >8 e⁻
- They have access to higher orbitals
- Cl, Br, I, P and S often do this:

- Trivalent boron is electron deficient and only has 6 e⁻ around it

Octet Rule Exceptions Problems

- H_2SO_4
- $\text{H}_3\text{CB}(\text{OH})_2$
- $\text{P}(\text{O})(\text{OH})_3$

Resonance Structures

- Often more than one equivalent Lewis structure can be written for one molecule
- The only difference between these structures is the position of e^- The connectivity remains constant

2

becomes

3

Resonance Structures

- An X-RAY of the carbonate ion reveals that all of the C/O bonds are the same length
- One wouldn't predict this by looking at individual Lewis structures

- Resonance theory states that all of these structures contribute to the actual molecule, which is represented by the **hybrid** wherein the bond lengths are part way between single and double bond lengths

Resonance Structure Rules

- Resonance structures exist only on paper (or iPads)
- Only electrons may be moved in drawing new RSs
- All must be proper Lewis structures
- The resonance hybrid is lower in energy than any one contributing resonance structure
 - The more covalent bonds the better
 - More filled valences the better
 - The less charge separation the better
- Lets draw resonance structures and the resonance hybrid for NO_3^- , SCN^- , CO , C_6H_6

Lewis Structures, Formal Charge & Resonance

- Let's draw the Lewis structures and resonance structures for ClO_3^- .

Valence e⁻ and Electronegativity

- **Electronegativity** - The measure of the ability of an atom to attract electrons
- Trend apparent on the Periodic Table
